

## Patient Information:

Name: Eshaan

Gender: Male

Age: 65

Consulting Doctor: Dr. Pranav Kumar

## Medical Findings:

**Clinical History:** The patient presented with localized pain and tenderness in the left upper extremity following trauma.

**Findings:** Imaging of the left upper extremity was performed. The study reveals a fracture involving the proximal aspect of the radius, classified as an extra-articular fracture. The fracture pattern is characterized as comminuted with multiple fragments. These findings are consistent with a comminuted extra-articular fracture of the proximal radius.

**Impressions:** Further clinical correlation and management, including potential orthopedic intervention, are recommended. Consultation with an orthopedic specialist for further evaluation and management planning is advised. Consideration for additional imaging studies, such as CT or MRI, if warranted for further characterization of the fracture pattern and assessment of soft tissue involvement is also recommended. Initiation of appropriate pain management and immobilization measures as indicated is essential.

**Conclusion:** The imaging findings demonstrate a comminuted extra-articular fracture of the proximal radius. Clinical correlation and orthopedic consultation are advised for further management.

## Severity:

Normal
